

**On the Tension Between Due Process Protection and Public Safety:  
The Case of an Extensive Procedural Reform in Colombia**

**ONLINE APPENDIX**

**This version: June 2026**

**Figure A1. Implementation of the Adversarial Procedural Reform in Colombia, 2005-2008**

**Note:** This map shows all the municipalities in Colombia by the stage of the implementation of the adversarial procedural reform, starting with municipalities in stage 1 which implemented the reform in January of 2005 and ending with municipalities in stage 4 which implemented it in January of 2008.

**Figure A2. Pre-Reform vs. Post-Reform Criminal Process (Law 600/00 vs. Law 906/04)**

**Note:** The criminal process under Law 600 and Law 906, drawn to scale on a common month axis. Under Law 600 the inquisitorial process is written and largely open-ended: after a roughly six-month preliminary phase and an 18–24-month written-dossier stage, the trial phase is bounded only by the statute of limitations. Law 906 introduces a two-step charging process with statutory deadlines: once charges are imputed, the prosecutor must file the indictment within 90 days, and the oral trial must begin within 120 days of indictment, after which the oral trial lasts 3 days to 4 months. Imputation (charge) is marked in both regimes. The phases bounded only by prescription—the pre-imputation investigation under Law 906 and the written trial under Law 600, each running until the statute of limitations (the maximum penalty, 5–20 years)—are shown out of scale.

**Table A1. Joint Test of Pre-Reform Trends**

| Outcome              | F-statistic | p-value |
|----------------------|-------------|---------|
| Arrests              | 0.90        | 0.479   |
| Unweighted Crime     | 0.46        | 0.931   |
| Crime Index          | 0.48        | 0.910   |
| Violent Crime Index  | 0.98        | 0.467   |
| Property Crime Index | 0.32        | 0.996   |

**Note:** this table reports joint F-tests of the null hypothesis that all coefficients on the leads of the reform indicator in the event-study specification are jointly equal to zero. The test, therefore, evaluates whether outcomes exhibit systematic pre-treatment trends prior to the implementation of the adversarial procedural reform. Failure to reject the null hypothesis supports the parallel trends assumption underlying the difference-in-differences design. All regressions include municipality, year, month, and year\*month fixed effects, as well as the same control variables used in the baseline specifications. Standard errors are clustered at the judicial district and month-of-year level.

## Data Construction

### Aggregated Crime

We created aggregated weighted crime as in Ortega, Mejía, and Ortiz (2015), following:

$$C_{i,t} = \sum_{s \in C} \left( \frac{p_s}{\sum_{s' \in C} p_{s'}} * S_{i,t} \right) \quad (1A)$$

where  $C_{i,t}$  represents one of the three crime indices (total, violent, or property) in municipality  $i$  and month  $t$ ;  $S_{i,t}$  is the crime rate for type of crime  $s$ , in municipality  $i$ , during month  $t$ , expressed in terms of incidences per 100,000 inhabitants, and  $p_s$  is the average sentence length in years for individuals convicted for crime  $s$ . Following the Colombian Penal Code, we include homicides and assaults as violent crimes, and muggings, business robberies, home burglaries and vehicle thefts as property crimes. We acknowledge that in the U.S. legal system, robberies are typically classified as violent crimes, and muggings occupy a somewhat ambiguous categorization. However, under the Colombian Penal Code, both robberies and muggings (*hurto* and *atraco*) are codified as crimes against property (*delitos contra la propiedad*). This distinction is not merely taxonomic—it has direct procedural implications, as the pretrial detention rules, plea agreements, and conciliation procedures applicable to these offenses are governed jointly with other property crimes under Colombian law.

We calculated average sentence length using the Penal Code of 2007. To calculate the maximum sentence length, we used the maximum prison sentence for each crime corrected by the maximum prison sentence in case of an aggravating circumstance. Table A2 reports these weights ( $p_s$ ).

**Table A2. Minimum and Maximum Sentence Length Colombian Penal Code**

| Crime              | Min | Max | Average( $p_s$ ) |
|--------------------|-----|-----|------------------|
| Homicides          | 13  | 40  | 27               |
| Assaults           | 1   | 15  | 8                |
| Muggings           | 1   | 16  | 9                |
| Business Robberies | 2   | 28  | 15               |
| Home Burglaries    | 6   | 14  | 10               |
| Vehicle Thefts     | 7   | 15  | 11               |
| Total              | 30  | 128 | 80               |

Note: this table shows the minimum and maximum sentence length for different types of crimes according to the Colombian Penal Code 2007, Articles 103, 111-116, 239-241. These lengths are used to build the weights for the crime indices.

### Indicators of Judicial and Prosecutorial Activity

First, we constructed rates allowing for information delays and timespans between denominator and numerator (CEPEJ 2014; Marciano et al. 2019):

$$\text{Clearance Rate}_{i,t}^s = \frac{\sum_{t=0}^{-11} \text{Imputations}_{i,t}^s}{\sum_{t=-1}^{11} \text{Crime Reports}_{i,t}^s} \quad (2A)$$

$$\text{Settlement Rate}_{i,t}^s = \frac{\sum_{t=0}^{-11} \text{Settlements}_{i,t}^s}{\sum_{t=-1}^{11} \text{Crime Reports}_{i,t}^s} \quad (3A)$$

$$\text{Acquittals or Convictions Rate}_{i,t}^s = \frac{\sum_{t=0}^{-11} \text{Acquittals or Convictions}_{i,t}^s}{\sum_{t=-1}^{11} \text{Crime Reports}_{i,t}^s} \quad (4A)$$

In the second group, we proposed rates controlling for the total number of cases when no logical time-gap between denominator and numerator exists:

$$\text{Preventive Measures}_{i,t}^s = \frac{\text{Cases with Active Measures}_{i,t}^s}{\text{Cases with Imputations}_{i,t}^s} \quad (5A)$$

$$\text{Acquittals or Convictions Ratio}_{i,t}^s = \frac{\text{Acquittals or Convictions in Court}_{i,t}^s}{\text{Acquittals+ Convictions in Court}_{i,t}^s} \quad (6A)$$

**Figure A3. Evolution of the Average Number of Crimes by Stage of Implementation**

**Note:** these figures show the average value of the four aggregate crime measures by stages of implementation of the adversarial procedural reform in Colombia, using a three-month moving average (MA-3) and normalizing the value in the month before implementation (represented by the grey vertical band) to 1. These crime indices are computed as weighted averages of different types of crime, with weights given by the average sentence length for each type and presented in Table A2.

**Figure A4. Evolution of the Average Number of Crimes in Colombia's Largest Cities**

**Note:** these figures show the average values of the four aggregate crime measures across Colombia's five largest cities: Bogotá, Medellín, Cali, Barranquilla, and Cartagena. The number in parentheses denotes the stage of implementation to which the municipality belongs. These series were plotted after taking a three-month moving average (MA-3) and normalizing the value in the month before implementation to 1 (represented by the grey vertical band). These crime indices are computed as the weighted average of different types of crimes, where the weights are given by the average sentence length of each type of crime and are presented in Table A2

### ***Data Comparability Across Sources***

We use prosecutorial administrative data on judicial decisions and judicial outcomes from the inquisitorial model information system (SIJUF) and the adversarial model information system (SPOA). Because our empirical strategy combines prosecutorial outcomes across the staggered implementation of the reform, it is important to clarify that the estimated effects are unlikely to be driven by mechanical discontinuities in coding, classification, or timestamp recording across SIJUF and SPOA.

Offense classifications are identical across SIJUF and SPOA. The procedural reform did not modify substantive criminal law, and crimes continue to be defined under the same articles of the Colombian Penal Code. Offense identifiers in both systems correspond to the same statutory provisions. Consequently, offense-level aggregation is mechanically comparable across systems, and no translation or recategorization of crime types is required.

To ensure comparability, the General Prosecutor's Office standardized outcome categories across SIJUF and SPOA. Person-level records are harmonized using a unified label ("indiciado") across systems. Disposition categories, including indictment, acquittal, conviction, dismissal, and settlement, are recorded under identical outcome labels in the harmonized data. The alignment of these categories reflects administrative standardization performed by the Prosecutor's Office rather than researcher-driven recoding.

Timestamp variables are recorded consistently across systems. Dates associated with case initiation, procedural actions, and case dispositions are stored under the same format in both systems. Duration measures are derived from standardized timestamp fields. There is no change in temporal granularity or recording conventions coinciding with the procedural transition.

To further assess comparability, we obtained prosecutorial data in three independent formats: (i) case-level records, (ii) judicial action-level records (actuaciones judiciales), and (iii) person-level records (imputado/indiciado). These datasets differ in unit of observation but contain overlapping information. Aggregated totals by municipality and month match closely across these extractions, and variable names, offense coding, and procedural categories are aligned across SIJUF and SPOA within each format, reducing the likelihood that observed patterns are driven by system architecture or file structure.

The crime outcomes analyzed in the paper are drawn from police administrative records, which are institutionally independent of prosecutorial information systems. These crime measures are not constructed using SIJUF or SPOA data.

Finally, we validate the pretrial detention measures using independent prison administrative records. Pretrial detention in prosecutorial data corresponds to individuals remanded to detention facilities prior to conviction. We replicate the analysis using prison admissions and stock measures of pretrial detainees and obtain patterns consistent with those reported using prosecutorial data

(see Table 2). Because prison administrative records are institutionally separate from prosecutorial information systems, the alignment of results across these independent sources provides additional evidence that observed changes in pretrial detention reflect real institutional changes rather than recording artifacts associated with the transition between SIJUF and SPOA.

Taken together, the identical substantive offense coding, the administrative harmonization of procedural categories, the uniform timestamp structure, the consistency across independent prosecutorial data extractions, and the corroboration of detention patterns using independent prison records mitigate concerns that the estimated effects reflect mechanical differences between information systems rather than changes associated with the procedural reform.

### ***Parallel Trends***

Besides the main results we obtain from equation (1), we use this model to estimate statistical differences during the pre-treatment period for variables contained in vector  $X_{i,t}$  and the lag of arrests ( $Z_{i,t-1}$ ). For variables in vector  $X_{i,t}$ , we use the yearly-municipality information provided by the CEDE between 2000-2004 and restrict the analysis to the pre-treatment period. Figure A5 illustrates that our treatment and control groups had parallel trends in all variables during the five years before the implementation of the reform, except for population density.

In addition to the unconditional evaluation of the parallel trends and phase-in effects, we estimate a version of equation (1) that includes a vector  $X_{i,t}$  containing the aforementioned economic, demographic, and institutional variables to control for time-varying municipality characteristics. Additionally, we incorporate the lag of police arrests to avoid endogeneity with this variable (Listokin 2003; Pfaff 2008; Rosenfeld and Wallman 2019). We perform this estimation and confirm that the parallel trends assumption seems to be reasonable even after the inclusion of the variables in  $X_{i,t}$ . Table A3 presents these results, confirming those presented in Figures 6 to 8 from the main text.

**Figure A5. Leads-and-Lags Pre-Treatment Evaluation for Control Variables**

**Note:** these figures show the coefficients of different regressions between each one of the control variables on time dummies for each period before the implementation of the procedural reform in Colombia. Except for arrests, which are available monthly, all variables are on a year-municipality level.

**Table A3. Conditional Event Study Results During the Pre-Treatment Period**

| Months Before Implementation | (1)<br>Unweighted Crime | (2)<br>Crime Index | (3)<br>Violent Crime | (4)<br>Property Crime | (5)<br>Homicides  | (6)<br>Assaults   | (7)<br>Sexual Offenses | (8)<br>Drug Offenses | (9)<br>Muggings   | (10)<br>Business Robberies | (11)<br>Vehicles Thefts | (12)<br>Home Burglaries |

| Municipality FE              | YES                     | YES                | YES                  | YES                   | YES               | YES               | YES                    | YES                  | YES               | YES                        | YES                     | YES                     |
| Controls                     | YES                     | YES                | YES                  | YES                   | YES               | YES               | YES                    | YES                  | YES               | YES                        | YES                     | YES                     |

Note: this table shows the results of a two-way fixed effects regression of different crime rates on interactions between an indicator variable that equals 1 if the adversarial procedural reform has been implemented in a given municipality and month, and dummy variables of each month before the implementation of the procedural reform. All regressions control for municipality, year, month, and year\*month fixed effects, as well as for per capita Industry and Business tax collection, per capita investment in education, fiscal performance, population density, rural index, displaced population, and the lagged police arrest rate. Standard errors are clustered at the judicial district times month of the year level. Crime indices are computed as weighted averages of different types of crime, with weights given by the average sentence length for each type and presented in Table A2. \*\*\* p<0.01, \*\* p<0.05, \* p<0.1

### ***Robustness, Placebo Tests and Alternative Specifications***

To test the robustness of our results, we present the results of the main specification from equation (2), excluding the lags of arrests. Results are robust to the exclusion of this variable.

In a second falsification test, we randomly assign all Colombian municipalities to different waves and estimate equation (1) using this random order. We repeat this random assignment 100 times and, in Table A5, present the average coefficients and standard errors across these 100 estimations. After these 100-estimations, we do not find a consistent pattern indicating spurious results.

Third, we preserve the geographic cohort structure of the actual rollout and assign placebo implementation dates to the first three cohorts within the available pre-reform period, while the fourth cohort remains untreated and serves as the comparison group. Tables A6 to A8 show that the placebo estimates are generally small and statistically indistinguishable from zero. Although a few isolated coefficients are statistically significant, they do not exhibit a systematic pattern and do not reproduce the crime effects obtained using the actual implementation dates.

Fourth, Tables A9 to A11 show that our results are robust to excluding Bogota, Medellin and Cali, Colombia's three largest cities and where most crime is located. In addition, Tables A12 to A14 show that the results also hold when excluding the vector of control variables  $X_{i,t}$  and the lag of arrests.

Moreover, we include different empirical exercises to test the robustness of our results, recognizing the staggered nature of our treatment. First, Figures A6 and A7 presents a graphic representation of the Goodman-Bacon (2021) decomposition for the different outcomes of interest. These decompositions reveal the substantial variance in optimal weights across comparison groups and motivate the use of alternative estimation methods.

Second, we estimate the event-study specifications using the doubly robust estimator proposed by Callaway & Sant'Anna (2021), which weights these comparisons by both the variance and the centrality of the treatment. In these estimations, we cluster the standard errors at the judicial district times month of the year level (figures A8 to A11). Figures A12 to A24 show results similar to those in the text, but with slightly larger standard errors and a wider time window.

Then, we estimate our differences-in-differences specification using the methodology proposed by Wooldridge (2025), who states that a highly flexible Difference-in-Difference model can account for this issue and produce similar estimates than those from the above-mentioned authors, but with lower standard errors. Table A15 contains the results. In Tables A16 to A18, we estimate our difference-in-differences specifications assuming that the data follow a Poisson distribution. This assumption allows us to verify how the main results change when accounting for the large proportion of zeros in some variables. The main results remain robust to changes in the distributional

assumption. Finally, Tables A19 to A21 present the main results, but with clustering at the judicial district  $\times$  year  $\times$  month level. The results and significance remain robust to this clustering.

These exercises confirm that the staggered-design critique does not overturn our findings. Across crime indices, the Callaway & Sant'Anna (2021) and Wooldridge (2025) estimates share the sign and statistical significance of the two-way fixed-effects baseline and are close in magnitude — for the weighted aggregate crime index, a coefficient of 0.46 under the two-way fixed effects model versus 0.35 under Wooldridge (2025). Standard errors are somewhat larger under the robust estimators (0.091 versus 0.080 for the weighted crime index), which is expected: they achieve robustness by discarding not-yet-treated comparisons, and because every district is treated by 2008, they rely on a shrinking control pool that thins out precisely in the later post-period where the dynamics of interest occur. We therefore maintain two-way fixed effects as our baseline, treating these estimators as confirmation rather than replacement.

Note: this table shows the results of a two-way fixed effects regression of different crime rates on an indicator variable that equals 1 if the adversarial procedural reform has been implemented in a given municipality and month (all columns) and the non-negative difference between a given month and the month of implementation up to 12 months (only in panel B). All regressions control for municipality, year, month, and year\*month fixed effects, as well as per capita Industry and Business tax collection, per capita investment in education, fiscal performance, population density, rural index, displaced population, and exclude the lagged police arrest. Standard errors are clustered at the judicial district times month of the year level. Crime indices are computed as weighted averages of different types of crime, with weights given by the average sentence length for each type and presented in Table A2. \*\*\* p<0.01, \*\* p<0.05, \* p<0.1

**Note:** This table reports placebo difference-in-differences estimates for the aggregate crime indices in columns (1)–(4) and the corresponding baseline estimates based on the actual implementation dates of the reform in columns (5)–(8). The placebo design preserves the geographic cohort structure of the actual rollout. Municipalities assigned to the first, second, and third implementation stages are assigned placebo implementation dates of July 2003, January 2004, and July 2004, respectively. Municipalities assigned to the fourth implementation stage remain untreated throughout the placebo period and constitute the comparison group. The placebo treatment indicator equals one from the cohort-specific placebo implementation date onward, whereas the baseline treatment indicator equals one after the reform was actually implemented in a municipality. The placebo estimates use the available pre-reform crime data, while the baseline estimates use the main estimation sample. All regressions include municipality fixed effects, calendar year-month fixed effects, and the same municipality-level controls included in the baseline specification. Standard errors, clustered according to the baseline clustering structure, are reported in parentheses. \*\*\*  $p < 0.01$ , \*\*  $p < 0.05$ , \*  $p < 0.1$ .

| Effect of Reform           | 30%                        | 19%                   | 15%                           | 28%                            | 44%                        | 27%                   | 16%                           | 57%                            |

Note: this table shows the results of a two-way fixed effects regression of different crime rates on an indicator variable that equals 1 if the adversarial procedural reform has been implemented in each municipality and month (all columns) and the non-negative difference between a given month and the month of implementation up to 12 months (columns 5 to 8). Regressions exclude Colombia's largest cities: Bogota, Medellin, and Cali. All regressions control for municipality, year, month, and year\*month fixed effects, as well as for per capita Industry and Business tax collection, per capita investment in education, fiscal performance, population density, rural index, displaced population, and the lagged police arrest rate. Standard errors are clustered at the judicial district times month of the year level. Mean T=0 corresponds to the mean of the dependent variable for those observations in the control group before the implementation of the reform. Effect of T is calculated as  $\frac{\beta_1}{\text{Mean } T = 0} * 100$  for columns (1) to (4) and as  $\frac{\beta_1 + (\beta_2 * 12)}{\text{Mean } T = 0} * 100$  for columns (5) to (8). Crime indices are computed as weighted averages of different types of crime, with weights given by the average sentence length for each type and presented in Table A2. \*\*\* p<0.01, \*\* p<0.05, \* p<0.1

Note: this table shows the results of a two-way fixed effects regression of different crime rates on an indicator variable that equals 1 if the adversarial procedural reform has been implemented in a given municipality and month (all columns) and the non-negative difference between a given month and the month of implementation up to 12 months (columns 5 to 8). Regressions exclude Colombia's largest cities: Bogota, Medellin, and Cali. All regressions control for municipality, year, month, and year\*month fixed effects, as well as for per capita Industry and Business tax collection, per capita investment in education, fiscal performance, population density, rural index, displaced population, and the lagged police arrest rate. Standard errors are clustered at the judicial district times month of the year level. Mean T=0 corresponds to the mean of the dependent variable for those observations in the control group before the implementation of the reform. Effect of T is calculated as  $\frac{\beta_1}{\text{Mean } T = 0} * 100$  for columns (1) to (4) and as  $\frac{\beta_1 + (\beta_2 * 12)}{\text{Mean } T = 0} * 100$  for columns (5) to (8). \*\*\* p<0.01, \*\* p<0.05, \* p<0.1

Note: this table shows the results of a two-way fixed effects regression of different crime rates on an indicator variable that equals 1 if the adversarial procedural reform has been implemented in each municipality and month (all columns) and the non-negative difference between a given month and the month of implementation up to 12 months (columns 5 to 8). All regressions control for only municipality, year, month, and year\*month fixed effects. Standard errors are clustered at the judicial district times month of the year level. Mean T=0 corresponds to the mean of the dependent variable for those observations in the control group before the implementation of the reform. Effect of T is calculated as  $\frac{\beta_1}{Mean\ T = 0} * 100$  for columns (1) to (4) and as  $\frac{\beta_1 + (\beta_2 * 12)}{Mean\ T = 0} * 100$  for columns (5) to (8). \*\*\* p<0.01, \*\* p<0.05, \* p<0.1

Figure A7. Goodman-Bacon (2021) Decomposition (continuation)

**Note:** these figures show the result of the Goodman-Bacon (2021) decomposition for different types of crimes. Crime indices are computed as the weighted average of different types of crimes, where the weights are given by the average sentence length of each type of crime and are presented in Table A2. The horizontal axis shows the weight assign by the decomposition, while the vertical axis shows the estimate given by the comparison of a particular pair of treatment-control groups.

**Figure A8. Event Study Estimation using Callaway & Sant'Anna (2021) Methodology: Aggregated Crime Measures**

**Note:** this figure shows the results of an event study of the logarithm of different crime rates as a function of the leads and lags relative to the month of implementation of the reform in a municipality, estimated using Callaway & Sant'Anna's (2021) doubly robust estimator. Dashed lines represent 95% confidence intervals computed with standard errors clustered at the judicial district times month of the year level. Crime indices are computed as the weighted average of different types of crime, with weights determined by the average sentence length for each type.

**Figure A9. Event Study Estimation using Callaway & Sant'Anna (2021) Methodology: Violent Crimes**

**Note:** this figure shows the results of an event study of the logarithm of different crime rates as a function of the leads and lags relative to the month of implementation of the reform in a municipality, estimated using Callaway & Sant'Anna's (2021) doubly robust estimator. Dashed lines represent 95% confidence intervals computed with standard errors clustered at the judicial district times month of the year level.

**Figure A10. Event Study Estimation using Callaway & Sant'Anna (2021) Methodology: Property Crimes**

**Note:** this figure shows the results of an event study of the logarithm of different crime rates as a function of the leads and lags relative to the month of implementation of the reform in a municipality, estimated using Callaway & Sant'Anna's (2021) doubly robust estimator. Dashed lines represent 95% confidence intervals computed with standard errors clustered at the judicial district times month of the year level.

**Figure A11. Event Study Estimation using Callaway & Sant'Anna (2021) Methodology: Arrests**

**Note:** this figure shows the results of an event study of the logarithm of different crime rates as a function of the leads and lags relative to the month of implementation of the reform in a municipality, estimated using Callaway & Sant'Anna's (2021) doubly robust estimator. Dashed lines represent 95% confidence intervals computed with standard errors clustered at the judicial district times month of the year level.

**Note:** this table shows the results of a two-way fixed effects regression of different crime rates on an indicator variable that equals 1 if the adversarial procedural reform has been implemented in each municipality and month, estimated using the methodology presented in Wooldridge (2025). All regressions control for municipality, year, month, and year\*month fixed effects, as well as for per capita Industry and Business tax collection, per capita investment in education, fiscal performance, population density, rural index, displaced population, and the lagged police arrest rate. Standard errors are clustered at the judicial district times month of the year level. Crime indices from Panel A are computed as weighted averages of different types of crime, with weights given by the average sentence length for each type and presented in Table A2.

\*\*\* p<0.01, \*\* p<0.05, \* p<0.1

**Figure A12. Leads-and-lags model: Procedural Times – Longer Run**

**Note:** this figure shows the results of an event study of the number of days between different stages of the criminal process, as a function of the leads and lags relative to the month of implementation of the reform in a municipality, over a 59-month time window. Dashed lines represent 95% confidence intervals. Standard errors are clustered at the judicial district times month of the year level.

**Figure A13. Leads-and-lags model: Pretrial detention in jail – Longer Run**

**Note:** this figure shows the results of an event study of the logarithm of the rates of pre-trial detentions in jail for different crimes as a function of the leads and lags relative to the month of implementation of the reform in a municipality, over a 59-month time window. Dashed lines represent 95% confidence intervals. Standard errors are clustered at the judicial district times month of the year level. Pretrial detention rates are computed as the ratio of the number of cases with active measures in a municipality-month to the total number of cases with imputations in that same municipality-month.

**Figure A14. Leads-and-lags model: Pretrial house arrest – Longer Run**

**Note:** this figure shows the results of an event study of the logarithm of the rates of pre-trial house arrests for different crimes as a function of the leads and lags relative to the month of implementation of the reform in a municipality, over a 59-month time window. Dashed lines represent 95% confidence intervals. Standard errors are clustered at the judicial district times month of the year level. Pretrial detention rates are computed as the ratio of the number of cases with active measures in a municipality-month to the total number of cases with imputations in that same municipality-month.

**Figure A15. Leads-and-lags model: Pretrial detention total – Longer Run**

**Note:** this figure shows the results of an event study of the logarithm of the rates of total pre-trial detentions for different crimes as a function of the leads and lags relative to the month of implementation of the reform in a municipality, over a 59-month time window. Dashed lines represent 95% confidence intervals. Standard errors are clustered at the judicial district times month of the year level. Pretrial detention rates are computed as the ratio of the number of cases with active measures in a municipality-month to the total number of cases with imputations in that same municipality-month.

**Figure A16. Leads-and-lags model for Settlement rate – Longer Run**

**Note:** this figure shows the results of an event study of settlement rates for the two minor crimes in our data for which a settlement hearing before the imputation of charges hearing is mandatory under the new system (property crimes and assault) as a function of the leads and lags relative to the month of implementation of the reform in a municipality, over a 59-month time window. Dashed lines represent 95% confidence intervals. Standard errors are clustered at the judicial district times month of the year level. Settlement rates are computed as the ratio between settlements and open cases for a specific crime in a municipality allowing for information delays and timespans, i.e.,  $Settlement\ Rate_{i,t}^s = \frac{\sum_{t=0}^{-11} Settlements_{i,t}^s}{\sum_{t=-1}^{11} Open\ Cases_{i,t}^s}$ .

**Figure A17. Leads-and-lags model for Acquittal rates – Longer Run**

**Note:** this figure shows the results of an event study of the logarithm of acquittal rates for different crimes as a function of leads and lags relative to the month of implementation of the reform in a municipality, over a 59-month time window. Dashed lines represent 95% confidence intervals. Standard errors are clustered at the judicial district times month of the year level. Rates are computed as the ratio between the total number of acquittals and open cases for a specific crime in a municipality allowing

for information delays and timespans, i.e.,  $Acquittals\ Rate_{i,t}^s = \frac{\sum_{t=0}^{-11} Acquittals_{i,t}^s}{\sum_{t=-1}^{11} Open\ Cases_{i,t}^s}$ .

**Figure A18. Leads-and-lags model for conviction rates – Longer Run**

**Note:** this figure shows the results of an event study of the logarithm of conviction rates for different crimes as a function of the leads and lags relative to the month of implementation of the reform in a municipality, over a 59-month time window. Dashed lines represent 95% confidence intervals. Standard errors are clustered at the judicial district times month of the year level. Rates are computed as the ratio between the total number of convictions and open cases for a specific crime in a municipality allowing for information delays and timespans, i.e.,  $Convictions\ Rate_{i,t}^s = \frac{\sum_{t=0}^{-11} Convictions_{i,t}^s}{\sum_{t=-1}^{11} Open\ Cases_{i,t}^s}$ .

**Figure A19. Leads-and-lags model for the share of acquittals in trial over total sentences in trial – Longer Run**

**Note:** this figure shows the results of an event study of the logarithm of in-trial acquittals for different crimes as a function of leads and lags relative to the month of implementation of the reform in a municipality, over a 59-month time window. Dashed lines represent 95% confidence intervals. Standard errors are clustered at the judicial district times month of the year level. Rates are computed as the ratio between the number of in-trial acquittals and open cases for a specific crime in a municipality

allowing for information delays and timespans, i.e.,  $Acquittals\ Rate_{i,t}^S = \frac{\sum_{t=0}^{-11} Acquittals_{i,t}^S}{\sum_{t=-1}^{11} Open\ Cases_{i,t}^S}$ .

**Figure A20. Leads-and-lags model for the share of convictions in trial over total sentences in trial  
– Longer Run**

**Note:** this figure shows the results of an event study of the logarithm of in-trial convictions for different crimes as a function of leads and lags relative to the month of implementation of the reform in a municipality, over a 59-month time window. Dashed lines represent 95% confidence intervals. Standard errors are clustered at the judicial district times month of the year level. Rates are computed as the ratio between the number of in-trial convictions and open cases for a specific crime in a municipality allowing for information delays and timespans, i.e.,  $Convictions\ Rate_{i,t}^s = \frac{\sum_{t=0}^{-11} Convictions_{i,t}^s}{\sum_{t=-1}^{11} Open\ Cases_{i,t}^s}$ .

**Figure A21. Leads-and-lags model for arrest rates – Longer Run**

**Note:** this figure shows the results of an event study of the logarithm of the arrest rate per 100,000 inhabitants as a function of the leads and lags relative to the month of implementation of the reform in a municipality, over a 59-month time window. Dashed lines represent 95% confidence intervals. Standard errors are clustered at the judicial district times month of the year level.

**Figure A22. Leads-and-lags model for Aggregate Crime Indices – Longer Run**

**Note:** this figure shows the results of an event study of the logarithm of crime rates as a function of leads and lags relative to the month of implementation of the reform in a municipality, over a 59-month time window. Dashed lines represent 95% confidence intervals. Standard errors are clustered at the judicial district times month of the year level. Crime indices are computed as the weighted average of different types of crime, with weights determined by the average sentence length for each type.

**Figure A23. Leads-and-lags model for Violent and Drug-related crimes – Longer Run**

**Note:** this figure shows the results of an event study of the logarithm of crime rates as a function of leads and lags relative to the month of reform implementation in a municipality, over a 60-month time window. Dashed lines represent 95% confidence intervals. Standard errors are clustered at the judicial district times month of the year level.

**Figure A24. Leads-and-lags model for Property crimes – Longer Run**

**Note:** this figure shows the results of an event study of the logarithm of crime rates as a function of leads and lags relative to the month of implementation of the reform in a municipality, over a 59-month time window. Dashed lines represent 95% confidence intervals. Standard errors are clustered at the judicial district times month of the year level.

**Note:** this table shows the results of a regression of different crime rates on an indicator variable that equals 1 if the adversarial procedural reform has been implemented in each municipality and month (all columns) and the non-negative difference between a given month and the month of implementation up to 12 months (columns 5 to 8). For this approach, we assume a Poisson data distribution. All regressions control for only municipality, year, month, and year\*month fixed effects. Standard errors are clustered at the judicial district times month of the year level. Mean T=0 corresponds to the mean of the dependent variable for those observations in the control group before the implementation of the reform. Effect of T is calculated as  $\frac{\beta_1}{Mean\ T = 0} * 100$  for columns (1) to (4) and as  $\frac{\beta_1 + (\beta_2 * 12)}{Mean\ T = 0} * 100$  for columns (5) to (8). Crime indices are computed as the weighted average of different types of crime, with weights given by the average sentence length for each type and presented in Table A2. \*\*\* p<0.01, \*\* p<0.05, \* p<0.1

Note: this table shows the results of a regression of different crime rates on an indicator variable that equals 1 if the adversarial procedural reform has been implemented in each municipality and month (all columns) and the non-negative difference between a given month and the month of implementation up to 12 months (columns 5 to 8). For this approach, we assume a Poisson data distribution. All regressions control for only municipality, year, month, and year\*month fixed effects. Standard errors are clustered at the judicial district times month of the year level. Mean T=0 corresponds to the mean of the dependent variable for those observations in the control group before the implementation of the reform. Effect of T is calculated as  $\frac{\beta_1}{\text{Mean } T = 0} *$

100 for columns (1) to (4) and as  $\frac{\beta_1 + (\beta_2 * 12)}{\text{Mean } T = 0} * 100$  for columns (5) to (8). \*\*\* p<0.01, \*\* p<0.05, \* p<0.1
